TEAM TIPS

- Absolutely make sure you earth the amplifier to a solid ground point. DO NOT use boot lock bolts, rear seat mount brackets or seat belt anchors. You must provide bare metal and a bolt-through fastening to allow the amplifier to provide full power. Poor earth quality is absolutely the #1 [non warrantable] killer of amplifiers.
- An easy way to accurately find the crossover point is to play a test tone of the frequency you want the crossover to be at and slowly increase or decrease the crossover frequency until the tone starts to go quiet meaning you are at the correct point.
- Amplifier performance and longevity is highly correlated to earth point quality. The best installers make their earth points to bare metal on the chassis using a nut and bolt.
- It is important not to try and make an amplifier work harder than its design allows, by using too much gain. Excessive gain causes clipping which destroys speakers and amplifiers very quickly.
- Always remember - if you want more volume, add cone area (more speakers). If you want tighter sound and more impactful transients, add power (more amplifiers).
